Late Breaker: We are seeing a significant increase in the number of kids testing positive for respiratory rhinoviruses/enteroviruses with many presenting with severe respiratory disease and asthma exacerbations. Internal surveillance at CHCO suggests that these increased infections are being driven by the reappearance of EV-D68. EV-D68 is an emerging, respiratory enterovirus that caused large outbreaks of respiratory disease in 2014 followed by reappearance every other year (seen again in 2016 and 2018). EV-D68 did not appear in 2020 as predicted, likely due to nonpharmaceutical interventions, such as masking, put in place to combat the spread of SARS-CoV-2. There is high probability that this is the start of a long and large outbreak of EV-D68.
