Late Breaker: CDPHE recently reported the first case of West Nile Virus (WNV) in Colorado in 2024 in a resident in Arapahoe county. During the summer, WNV should be on the differential diagnosis of anyone who presents with an acute febrile or neurologic illness particularly if they have known recent exposure to mosquitoes. IgM serology is the recommended diagnostic test for suspected patients. In other mosquito news, the Americas are experiencing the largest outbreak of dengue ever reported – with twice the number of cases already reported this year compared to all of last year. This has corresponded to higher-than-expected number of travel related dengue cases being reported in the U.S. Now is a good time to promote mosquito bite prevention measures both here in Colorado as well as in those who are travelling abroad to countries experiencing large numbers of dengue cases.
