**Late Breaker:** The Omicron subvariant BA.2.12.1 now makes up over 60% of the cases in the U.S with the number of COVID-19 cases in Colorado and throughout the US continuing to rise. Currently 25% of US counties (including Colorado counties: Arapahoe, Boulder, Denver, Douglas, Jefferson, and Larimer) fall within the CDC’s medium to high “COVID-19 Community Levels.” After reports of several small outbreaks of monkeypox were reported in Europe, a case of monkeypox was reported in a U.S. resident in Massachusetts after travel to Canada. The rash associated with monkeypox typically involves vesicles or pustules that are deep-seated, firm, or hard and well circumscribed. The rash can sometimes be confused with the rash associated with secondary syphilis, herpes, chancroid or varicella. If a case of monkeypox is suspected, clinicians should consult with their state health department and collect samples for testing (https://www.cdc.gov/poxvirus/monkeypox/outbreak/current.html).
