Late Breaker: Last week CDPHE released an updated HAN on Neisseria meningitidis infections due to an increase in invasive meningococcal disease with 14 cases this year compared to an average of 5-10 cases per year. Patients presented with a variety of clinical manifestations, including bacteremia, meningitis, septic arthritis, and pneumonia and six cases were in people experiencing homelessness or housing insecurity. Additionally, a recent CDC HAN links cases of meningococcal disease with travel to the Kingdom of Saudia Arabia (KSA) and reminds people 1 year old and older to be vaccinated with MenACWY conjugate vaccines who are considering travel to KSA to perform Hajj or Umrah.
